From retouching to changing a photo's background, you'll discover all sorts of functions, including the ones shown in this chapter. Understanding Image Editing with Photoshop An image is any visual item that represents reality. Your ability to create the illusion of reality in a two-dimensional image is an important part of being a photographer, and Photoshop makes this process a lot easier. The tools available for image manipulation within Photoshop are many, but you can find that they essentially fall into two categories: Adjustments tools: These tools allow you to perform adjustments, such as correcting exposure, color, contrast, sharpness, and so on. Features: These tools are available for producing effects, such as turning a photo into a silhouette or superimposing a background. You can create a photo using all three types of tools, but they each have their place and purpose, so we explain what they are and how you use them. Creating the illusion of reality Even the most talented of photographers has to make some decisions about how a photograph looks. In other words, a natural-looking photo that looks like the real thing is one that has been taken through the camera's lens and exposed with the correct exposure, right color balance, and right lighting. If a photo seems too light or too dark, then it may be that either the exposure or the color balance has been adjusted. When you shoot a photo, you may notice that one area looks a little bright or a little dull. In that case, you can often reduce the brightness or increase the contrast in the photo. Whether you do this or let the camera do it automatically is a personal choice. Whatever you do, make sure that you have the proper tools and background knowledge to know when and how to use them. Adjusting exposure and color balance You can

[Morphology of the esophageal epithelium]. The mucosa of the esophagus presents structural and functional characteristics of great importance to the digestion process. This mucosa is characterized by having an epithelial layer of three cell types: goblet cells, ciliated cells and a basal layer with no specific differentiation. The mucosa has a high transcellular and a moderate paracellular permeability which makes it susceptible to continuous exposure to noxious agents in the reflux of stomach contents. The esophageal mucosa must be able to endure continuous exposure to substances which potentially damage it. This requires the synthesis of a mucus barrier as well as a physical barrier consisting of a covering at the epithelial surface which limits epithelial exposure to the outside environment. The esophageal epithelium is covered by a periostium, whose extension varies from the proximal to the distal part of the esophagus. The mucosa of the proximal region is characterized by a predominance of squamous epithelial cells with granular cytoplasm and a well-defined periostium. The granular cytoplasm could explain the high squamous epithelium renewal potential because of the high activity of the mitochondria and the pro-apoptotic factors activated by p53. In the mid portion, the ciliated epithelium predominates, possibly due to the stenosis caused by the presence of the lower esophageal sphincter. Finally, the distal esophagus presents a mix of squamous and columnar epithelial cells with the covering periostium reduced.Exotec Cameras We are Exotec, a company focused on providing high quality products and service for photographers in all aspects of photography.
