File from the Examples folder. Kriterion at the University of Leipzig. Statistics is the process of gathering and organizing information in order to test a theory or draw inferences from the data. Most used statistics include regression, correlation, covariance, and multiple

regression. This is used to make inferences about the relationship between two or more variables. The most common formats for storing data in statistics are for example. Data. Data can be shown in grids, graphs or tables. Multidimensional data are sometimes described in the context of a coordinate system. Data analysis starts with data collection, which is the process of getting information about the people being studied. The types of questions being asked will determine which collection methods will be used, such as surveys, questionnaires,

observation, or laboratory tests. When information is obtained, it is often organized, summarized, and presented in a format. How the data is presented will vary depending on the purpose of the study. Data analysis is the process of making inferences from the data collected. The most common tools for data analysis are hypothesis tests, graphical representations, and statistical tests. Hypothesis tests are used to help draw conclusions about the difference between two groups of data. Graphical representations are used to visualize data, such as

scatter plots, bar charts, pie charts, histograms, line graphs, and scatter plots. There are two types of statistical tests: parametric and non-parametric. Parametric statistics are descriptive statistics whose sample means tend to be normally distributed. Parametric tests depend on parametric assumptions about the data. Non-parametric statistics are not descriptive statistics and do not assume a parametric distribution. The statistics that are used for data analysis change depending on the type of data being compared. There are

many statistical tests, including hypothesis tests, the t-test, correlation, regression, and analysis of variance. The hypothesis test is used to investigate the difference between two groups, whether groups being studied differ, and if the results of a study show an association. Regression uses a statistical model to predict. This is used to make inferences about an unknown (latent) variable given a set of observed variables c6a93da74d
